IERG 5350 Assignment 2

October 13, 2020

1 IERG 5350 Assignment 2: Model-free Tabular RL

2020-2021 Term 1, IERG 5350: Reinforcement Learning. Department of Information Engineering, The Chinese University of Hong Kong. Course Instructor: Professor ZHOU Bolei. Assignment author: PENG Zhenghao, SUN Hao, ZHAN Xiaohang.

Student Name	Student ID
Yan XU	1155139432

Welecome to the assignment 1 of our RL course. The objective of this assignment is for you to understand the classic methods used in tabular reinforcement learning.

This assignment has the following sections:

- Section 1: Implementation of model-free familiy of algorithms: SARSA, Q-Learning and model-free control. (100 points)

You need to go through this self-contained notebook, which contains dozens of **TODOs** in part of the cells and has special `[TODO]` signs. You need to finish all TODOs. Some of them may be easy such as uncommenting a line, some of them may be difficult such as implementing a function. You can find them by searching the `[TODO]` symbol. However, we suggest you to go through the documents step by step, which will give you a better sense of the content.

You are encouraged to add more code on extra cells at the end of the each section to investigate the problems you think interesting. At the end of the file, we left a place for you to optionaly write comments (Yes, please give us some either negative or positive rewards so we can keep improving the assignment!).

Please report any code bugs to us via Github issues.

Before you get start, remember to follow the instruction at https://github.com/cuhkrlcourse/ierg5350-assignment to setup your environment.

1.1 Section 1: SARSA

(30/100 points)

You have noticed that in Assignment 1 - Section 2, we always use the function `trainer._get_transitions()` to get the transition dynamics of the environment, while never call `trainer.env.step()` to really interact with the environment. We need to access the internal feature of the environment or have somebody implement `_get_transitions` for us. However, this is not feasible in many cases, especially in some real-world cases like autonomous driving where the transition dynamics is unknown or does not explicitly exist.

In this section, we will introduce the Model-free family of algorithms that do not require to know the transitions: they only get information from `env.step(action)`, that collect information by interacting with the environment rather than grab the oracle of the transition dynamics of the environment.

We will continue to use the `TabularRLTrainerAbstract` class to implement algorithms, but remember you should not call `trainer._get_transitions()` anymore.

We will use a simpler environment `FrozenLakerNotSlippery-v0` to conduct experiments, which has a `4 X 4` grids and is deterministic. This is because, in a model-free setting, it's extremely hard for a random agent to achieve the goal for the first time. To reduce the time of experiments, we choose to use a simpler environment. In the bonus section, you will have the chance to try model-free RL on `FrozenLake8x8-v0` to see what will happen.

Now go through each section and start your coding!

Recall the idea of SARSA: it's an on-policy TD control method, which has distinct features compared to policy iteration and value iteration:

1. Maintain a state-action pair value function $Q(s_t, a_t) = E\sum_{i=0}\gamma^{t+i}r_{t+i}$, namely the Q value.
2. Do not require to know the internal dynamics of the environment.
3. Use an epsilon-greedy policy to balance exploration and exploitation.

In SARSA algorithm, we update the state action value (Q value) via TD error:

$$TD(s_t, a_t) = r(s_t, a_t) + \gamma Q(s_{t+1}, a_{t+1}) - Q(s_t, a_t)$$

where we run the policy to get the next action $a_{t+1} = Policy(s_{t+1})$. (That's why we call SARSA an on-policy algorithm, it use the current policy to evaluate Q value).

$$Q^{new}(s_t, a_t) = Q(s_t, a_t) + \alpha TD(s_t, a_t)$$

Wherein α is the learning rate, a hyper-parameter provided by the user.

Now go through the codes.

        self.learning_rate = learning_rate

        # build the Q table
        # [TODO] uncomment the next line, pay attention to the shape
        self.table = np.zeros((self.obs_dim, self.action_dim))

    def policy(self, obs):
        """Implement epsilon-greedy policy

        It is a function that take an integer (state / observation)
        as input and return an interger (action).
        """

        # [TODO] You need to implement the epsilon-greedy policy here.
        # hint: We have self.eps probability to choose a unifomly random
        #  action in range [0, 1, .., self.action_dim - 1],
        #  otherwise choose action that maximize the Q value
        if np.random.rand()<self.eps:
            act=np.random.choice(range(self.action_dim))
        else:
            act = np.argmax(self.table[obs])
        return act
        pass

    def train(self):
        """Conduct one iteration of learning."""
        # [TODO] Q table may be need to be reset to zeros.
        # if you think it should, than do it. If not, then move on.
        pass
        # No, we should do nothing.

        obs = self.env.reset()
        for t in range(self.max_episode_length):
            act = self.policy(obs)
```

```
            next_obs, reward, done, _ = self.env.step(act)
            next_act = self.policy(next_obs)

            # [TODO] compute the TD error, based on the next observation and
            #  action.
            td_error = None

            td_error = reward+self.gamma*self.table[next_obs][next_act]-self.
↪table[obs][act]
            pass

            # [TODO] compute the new Q value
            # hint: use TD error, self.learning_rate and old Q value
            new_value = None
            new_value=self.table[obs][act]+self.learning_rate*td_error
            pass

            self.table[obs][act] = new_value

            # [TODO] Implement (1) break if done. (2) update obs for next
            #  self.policy(obs) call
            if done:
                break
            else:
                obs=next_obs
            pass

# [TODO] run the next cell to check your code
```

Now you have finish the SARSA trainer. To make sure your implementation of epsilon-greedy strategy is correct, please run the next cell.

[5]:
```
# Run this cell without modification

# set eps = 0 to disable exploration.
test_trainer = SARSATrainer(eps=0.0)
test_trainer.table.fill(0)

# set the Q value of (obs 0, act 3) to 100, so that it should be taken by
# policy.
test_obs = 0
test_act = test_trainer.action_dim - 1
test_trainer.table[test_obs][test_act] = 100

# assertion
assert test_trainer.policy(test_obs) == test_act, \
    "Your action is wrong! Should be {} but get {}.".format(
```

```
        test_act, test_trainer.policy(test_obs))

# delete trainer
del test_trainer

# set eps = 0 to disable exploitation.
test_trainer = SARSATrainer(eps=1.0)
test_trainer.table.fill(0)

act_set = set()
for i in range(100):
    act_set.add(test_trainer.policy(0))

# assertion
assert len(act_set) > 1, ("You sure your uniformaly action selection mechanism"
                          " is working? You only take action {} when "
                          "observation is 0, though we run trainer.policy() "
                          "for 100 times.".format(act_set))
# delete trainer
del test_trainer

print("Policy Test passed!")
```

```
Policy Test passed!
```

Now run the next cell to see the result. Note that we use the non-slippery version of a small frozen lake environment `FrozenLakeNotSlipppery-v0` (this is not a ready Gym environment, see `utils.py` for details). This is because, in the model-free setting, it's extremely hard to access the goal for the first time (you should already know that if you watch the agent randomly acting in Assignment 1 - Section 1).

[6]:
```

```

[9]:
```
# Run this cell without modification

sarsa_trainer.render()
```

Now you have finished the SARSA algorithm.

1.2 Section 2: Q-Learning

(30/100 points)

Q-learning is an off-policy algorithm who differs from SARSA in the computing of TD error. Instead of running policy to get `next_act` a' and get the TD error by:

$r + \gamma Q(s', a') - Q(s, a)$,

in Q-learning we compute the TD error via:

$r + \gamma \max_{a'} Q(s', a') - Q(s, a)$.

The reason we call it "off-policy" is that the policy involves the computing of next-Q value is not the "behavior policy", instead, it is a "virtural policy" that always takes the best action given current Q values.

[10]:
```
# Solve the TODOs and remove `pass`

class QLearningTrainer(TabularRLTrainerAbstract):
    def __init__(self,
                 gamma=1.0,
                 eps=0.1,
                 learning_rate=1.0,
                 max_episode_length=100,
                 env_name='FrozenLake8x8-v0'
                 ):
        super(QLearningTrainer, self).__init__(env_name, model_based=False)
        self.gamma = gamma
        self.eps = eps
        self.max_episode_length = max_episode_length
        self.learning_rate = learning_rate

        # build the Q table
        self.table = np.zeros((self.obs_dim, self.action_dim))

Now you have finished Q-Learning algorithm.

1.3 Section 3: Monte Carlo Control

(40/100 points)

In sections 1 and 2, we implement the on-policy and off-policy versions of the TD Learning algorithms. In this section, we will play with another branch of the model-free algorithm: Monte Carlo Control. You can refer to the 5.3 Monte Carlo Control section of the textbook "Reinforcement Learning: An Introduction" to learn the details of MC control.

The basic idea of MC control is to compute the Q value (state-action value) directly from an episode, without using TD to fit the Q function. Concretely, we maintain a batch of lists (the total number of lists is `obs_dim * action_dim`), each elememnt of the batch is a list correspondent to a

state-action pair. The list is used to store the previously happenning "return" of each state action pair.

We will use a dict `self.returns` to store all lists. The keys of the dict are tuples `(obs, act)`: `self.returns[(obs, act)]` is the list to store all returns when `(obs, act)` happens.

The key point of MC Control method is that we take the mean of this list (the mean of all previous returns) as the Q value of this state-action pair.

The "return" here is the discounted return starting from the state-action pair: $Return(s_t, a_t) = \sum_{i=0} \gamma^{t+i} r_{t+i}$.

In short, MC Control method uses a new way to estimate the values of state-action pairs.

1.4 Secion 4 Bonus (optional): Tune and train FrozenLake8x8-v0 with Model-free algorithms

You have noticed that we use a simpler environment `FrozenLakeNotSlippery-v0` which has only 16 states and is not stochastic. Can you try to train Model-free families of algorithm using the `FrozenLake8x8-v0` environment? Tune the hyperparameters and compare the results between different algorithms.

Hint: It's not easy to train model-free algorithm in `FrozenLake8x8-v0`. Failure is excepted.

[115]:

```

Now you have implement the MC Control algorithm. You have finished this section. If you want to do more investigation like comparing the policy provided by SARSA, Q-Learning and MC Control, then you can do it in the next cells. It's OK to leave it blank.

[ ]:
```
# You can do more investigation here if you wish. Leave it blank if you don't.
```

1.5 Conclusion and Discussion

It's OK to leave the following cells empty. In the next markdown cell, you can write whatever you like. Like the suggestion on the course, the confusing problems in the assignments, and so on.

If you want to do more investigation, feel free to open new cells via `Esc + B` after the next cells and write codes in it, so that you can reuse some result in this notebook. Remember to write sufficient comments and documents to let others know what you are doing.

Following the submission instruction in the assignment to submit your assignment to our staff. Thank you!
